BEFORE & AFTER

What our application actually solves

A side-by-side picture of getting an Encumbrance Certificate the way it's done today, versus with our application — and exactly what problem each step removes.

The same job, two ways

One property lookup, step by step, side by side.

What we actually solved

Each problem on the left is real and happens today. Here's exactly what removes it.

THE PROBLEM, TODAY	HOW OUR APPLICATION SOLVES IT
A person has to sit and do this one property at a time — it doesn't scale without hiring more people.	The system handles many lookups in parallel. One person is only needed for the 10-second CAPTCHA check, not the whole job.
A "nothing found" result can get misread as "the property is clear" — a real legal risk.	The system never makes that call automatically. An unclear or empty result is flagged for a person to confirm before anyone relies on it.
There's no consistent record of what was searched, when, or what came back.	Every request, its result, and the document itself are saved automatically, every time — a complete audit trail with no extra effort.
Results have to be manually re-typed into whatever system the client actually uses.	The result is delivered straight into the ERP automatically, in the same structured format every time.
If the government site is slow or down, the person just has to wait, or try again later.	The system retries automatically and shows a live status, instead of a person babysitting a frozen page.

> **What we did not try to solve, on purpose:** the CAPTCHA step. That control exists to stop automated access, and we don't believe it should be defeated — only handed to a person, quickly and predictably, every time it appears.
